Abstract. This work introduces a novel hybrid conjugate gradient (CG) technique for tackling unconstrained optimisation problems with improved efficiency and effectiveness. The parameter θ_k is computed as a convex combination of the standard conjugate gradient techniques using β_k^{LS} and β_k^{Ha} . Our proposed method has shown that when using the strong Wolfe-line-search(SWC) under specific conditions, it achieves global theoretical convergence. In addition, the new hybrid CG approach has the ability to generate a search direction that moves downward with each iteration. The quantitative findings obtained by applying the recommended technique about 30 functions with varying dimensions clearly illustrate its effectiveness and potential.

Keywords: Numerical optimization, Unconstrained objective function, Hybrid gradient methods, Global convergence, Numerical experiment

1- INTRODUCTION

Assuming we have a general function $f: R^n \rightarrow R$ that is continuously differentiable. Also, examine the subsequent un-constrained optimisation issue

$$\min \text{ (or max) } \{f(x)\} \in R^n \quad (1)$$

The space R^n represent an “n-dimensional Euclidean space”.

To solve Equation (1), we begin by selecting an initial guess $x_0 \in R^n$. We then employ a non-linear conjugate gradient approach to produce a series $\{x_k\}$

$$x_{k+1} = x_k + \alpha_k d_k, \quad k = 0, 1, 2, \dots \quad (2)$$

The value of $\alpha_k > 0$ is determined by a process called “line search”. The direction denoted d_k are formed using a specific design as

$$d(x) = \begin{cases} -g_k, & k = 0 \\ -g_k + \beta_k d_k, & k > 0 \end{cases} \quad (3)$$

Let g_k be the gradient of $f(x_k)$, and β_k be a scalar parameter that defines the properties of conjugate gradient techniques.

In the field of computing, the step-size α_k is considered to meet any of the line search conditions during the procedure. This work focuses on the robust Wolfe line search Equation (4) [1].

$$f(x_k + \alpha_k d_k) \leq f(x) + \delta \alpha_k g_k^T d_k, \quad 0 \leq \delta \leq \frac{1}{2} \quad (4)$$

$$|d_k^T g(x_k + \alpha_k d_k)| \leq -\sigma g_k^T d_k, \quad 0 \leq \delta \leq 1$$

The search direction, denoted as d_k is explicitly defined in Equation (3).

Researchers have devoted significant attention to CG approaches for a long time. The result of such investigations is the development of numerous formulas with variations in the CG coefficient (β_k) for addressing unconstrained optimisation issues[2].

Here are several typical formulas for β_k :

$\beta_k^{ER} = \frac{g_{k+1}^T g_{k+1}}{g_k^T g_k},$	FR(Fletcher – Reeves) [3]
$\beta_k^{PR} = \frac{g_{k+1}^T y_k}{g_k^T g_k},$	PR (Polak – Ribiere) [4]
$\beta_k^{DY} = \frac{g_k^T g_k}{d_{k-1}^T y_{k-1}},$	DY (Dai – Yuan) [5]
$\beta_k^{CD} = \frac{-g_k^T g_k}{d_{k-1}^T g_{k-1}},$	CD (conjugate descent) [6]
$\beta_k^{LS} = \frac{-g_k^T y_{k-1}}{d_{k-1}^T g_{k-1}},$	LS (Liu – Storey) [7]
$\beta_k^{HS} = \frac{g_k^T y_{k-1}}{d_{k-1}^T y_{k-1}}$	HS(Hestenes- Stiefel) [8]

Were

$$y_{k-1} = g_k - g_{k-1}, \quad (5)$$

Despite their excellent global theroritic convergence, the computational performance of the CG approaches β_k^{LS} and β_k^{CD} is lower. however, superior computing performance is generally achieved by the β_k^{PR} , β_k^{LS} and β_k^{HS} , despite the fact that they haven't demonstrated convergence[9]. "In most cases, hybrid conjugate gradient methods are more efficient than basic conjugate gradient methods. The hybrid conjugates gradient techniques discussed in this study are of particular importance. These algorithms are a mixture of a number of different conjugate gradient techniques."[10]

The main principle behind their strategy is to capitalize on projected outcomes. They are frequently promoted as a means to prevent congestion. We have presented a novel hybrid CG approach that relies on the *Ha* and *LS* methods. The method incorporates the parameters β_k^{Ha} and β_k^{LS} .

$$\beta_k^{LS} = \frac{g_{k+1}^T y_k}{-d_k^T g_k}, \quad \beta_k^{Ha} = \frac{\|g_{k+1}\|^2}{(f_{k+1} - f_k/\alpha_k - 3/2)d_k^T g_k} \quad [11].$$

To solve the unconstrained optimization problems with β_k^{MR}

The parameter β_k^H in our proposed method is computed as a convex combination of β_k^{Ha} and β_k^{LS} such that

$$\beta_k^{MR} = (1 - \theta_k)\beta_k^{LS} + \theta_k \beta_k^{Ha} \quad (6)$$

We have $0 \leq \theta_k \leq 1$

The rest of the document is structured in the following manner. In section 2, we outline our suggested approach for acquiring the parameter θ_k using several methodologies. We further analyse the adequate descent property of our approach under certain suitable conditions, and moreover establish the parameter constraint in the form of $0 \leq \theta_k \leq 1$. Section 3 encompasses several assumptions, whereas section 4 defines the global convergence of the proposed approach. Section 5 concludes by presenting the results of numerical experiments that were conducted.

2. GRADIENT METHOD CONJUGATES WITH THE NEW HYBRID

2.1 The New θ_k Parameter Derivation

The recurrence is utilized to determine the iterates $x_0, x_1, x_2, \dots$ of our method (2.2). The strong Wolfe requirements (4) determine the step size $\alpha_k > 0$, whereas the rule generates the directions.

$$\begin{cases} d_0 = -g_0 \\ d_{k+1} = -g_{k+1} + \beta_k^H d_k \end{cases} \quad (7)$$

and the parameter β_k^H in the form Eq(6), where $0 \leq \theta_k \leq 1$ and we derived hybrid parameter by, derivation of the new parameter

$$B_k^{H_1} = (1 - \theta_k)B_k^{LS} + \theta_k B_k^{Ha}$$

$$B_k^{H_1} = (1 - \theta_k) \frac{g_{k+1}^T y_k}{-d_k^T g_k} + \theta_k \frac{\|g_{k+1}\|^2}{(f_{k+1} - f_k)/\alpha_k - 3/2 d_k^T g_k}$$

Derivation of the new hybrid parameter from the above equation

$$d_k = \begin{cases} -g_k & \text{if } k = 0 \\ -g_k + B_k^{H_1} d_{k-1} & \text{if } k > 0 \end{cases}$$

since $0 \leq \theta_k \leq 1$

$$d_{k+1} = -g_{k+1} + (1 - \theta_k) \frac{g_{k+1}^T y_k}{-d_k^T g_k} d_k + \theta_k \frac{\|g_{k+1}\|^2}{(f_{k+1} - f_k)/\alpha_k + 3/2 d_k^T g_k} d_k$$

Wolf's situation makes that imperative

$$f_{k+1} \leq f_k + \delta \alpha_k g_k^T d_k, \quad 0 \leq \delta \leq \frac{1}{2}$$

Multiply both sides of the equation y_k^T

$$y_k^T d_{k+1} = -y_k^T g_{k+1} + (1 - \theta_k) \frac{g_{k+1}^T y_k}{-d_k^T g_k} y_k^T d_k + \theta_k \frac{\|g_{k+1}\|^2}{\frac{\delta \alpha_k g_k^T d_k}{\alpha_k} - \frac{3}{2} d_k^T g_k} y_k^T d_k$$

It's essential the $y_k^T d_{k+1} = 0$ by perry, then

$$0 = -y_k^T g_{k+1} + (1 - \theta_k) \frac{g_{k+1}^T y_k}{-d_k^T g_k} y_k^T d_k + \theta_k \frac{\|g_{k+1}\|^2}{-\delta_1 g_k^T d_k} y_k^T d_k$$

$$0 = -y_k^T g_{k+1} - \frac{g_{k+1}^T y_k}{d_k^T g_k} y_k^T d_k + \theta_k \frac{g_{k+1}^T y_k}{d_k^T g_k} y_k^T d_k - \theta_k \frac{\|g_{k+1}\|^2}{\delta_1 g_k^T d_k} y_k^T d_k$$

$$y_k^T g_{k+1} + \frac{g_{k+1}^T y_k}{d_k^T g_k} y_k^T d_k = \theta_k \left[\frac{g_{k+1}^T y_k}{d_k^T g_k} y_k^T d_k - \frac{\|g_{k+1}\|^2}{\delta_1 g_k^T d_k} y_k^T d_k \right]$$

$$\therefore \theta_k = \frac{y_k^T g_{k+1} + \frac{g_{k+1}^T y_k}{d_k^T g_k} y_k^T d_k}{\frac{g_{k+1}^T y_k}{d_k^T g_k} y_k^T d_k - \frac{\|g_{k+1}\|^2}{\delta_1 g_k^T d_k} y_k^T d_k}$$

$$\theta_k = \frac{\frac{y_k g_{k+1}}{y_k^T d_k} + \frac{g_{k+1}^T y_k}{d_k^T g_k}}{\left[\frac{g_{k+1}^T y_k}{d_k^T g_k} + \frac{\|g_{k+1}\|^2}{(\delta \alpha_k g_k^T d_k / \alpha_k - 3/2 d_k^T g_k)} \right]} \quad (8)$$

In order to Prove that $0 \leq \theta_k \leq 1$ we will use the following mathematical lemma.

Lemma: The hybridization parameter in the convex structure is limited to 0 and 1. And so is our hybridization scalar Eq(8).

Proof

1-The first possibility:- we take the case of a fraction that is less than zero. we get a contradiction because a positive value + a positive value is impossible for a negative result to appear.

$$\frac{\text{Numerator} + \text{denominator}}{\text{Numerator} + \text{the rule}} \quad \begin{array}{c} \swarrow \searrow \\ \nwarrow \swarrow \end{array} < \frac{0}{1}$$

$$\frac{\frac{y_k g_{k+1}}{y_k^T d_k} + \frac{g_{k+1}^T y_k}{d_k^T g_k}}{\left[\frac{g_{k+1}^T y_k}{d_k^T g_k} + \frac{\|g_{k+1}\|^2}{(\delta \alpha_k g_k^T d_k / \alpha_k - 3/2 d_k^T g_k)} \right]}$$

The product of two sides multiplied by two means.

$$\frac{y_k g_{k+1}}{y_k^T d_k} + \frac{g_{k+1}^T y_k}{d_k^T g_k}$$

A contradiction because a positive value + a positive value

2-The second possibility: we take, the fraction greater than zero and obtain that the denominator is greater than zero

$$0 < \frac{\frac{y_k g_{k+1}}{y_k^T d_k} + \frac{g_{k+1}^T y_k}{d_k^T g_k}}{\left[\frac{g_{k+1}^T y_k}{d_k^T g_k} + \frac{\|g_{k+1}\|^2}{(\delta_{\alpha k} g_k^T d_k / \alpha_k - 3/2 d_k g_k^T)} \right]}$$

3-The third possibility:- we take the fraction less than one and obtain that the denominator is the greater than the numerator

$$\frac{\frac{y_k g_{k+1}}{y_k^T d_k} + \frac{g_{k+1}^T y_k}{d_k^T g_k}}{\left[\frac{g_{k+1}^T y_k}{d_k^T g_k} + \frac{\|g_{k+1}\|^2}{(\delta_{\alpha k} g_k^T d_k / \alpha_k - 3/2 d_k g_k^T)} \right]} < 1$$

$$\frac{\cancel{\text{the value}} + \cancel{\text{denominator}}}{\text{Numerator} + \cancel{\text{the value}}} < 1$$

$$\text{the value} + \text{denominator} < \text{the value} + \text{Numerator}$$

$$\text{denominator} < \text{Numerator}$$

$$\frac{y_k g_{k+1}}{y_k^T d_k} + \frac{\cancel{g_{k+1}^T y_k}}{\cancel{d_k^T g_k}} < \frac{\cancel{g_{k+1}^T y_k}}{\cancel{d_k^T g_k}} + \frac{\|g_{k+1}\|^2}{(\delta_{\alpha k} g_k^T d_k / \alpha_k - 3/2 d_k g_k^T)}$$

$$\frac{y_k g_{k+1}}{y_k^T d_k} < \frac{\|g_{k+1}\|^2}{(\delta_{\alpha k} g_k^T d_k / \alpha_k - 3/2 d_k g_k^T)}$$

4- The fourth possibility:- we take the fraction greater than one and obtain a contradiction due to the presence of the squared swelling. By simplifying, this result appears (a contradiction)

$$1 < \frac{\frac{y_k g_{k+1}}{y_k^T d_k} + \frac{g_{k+1}^T y_k}{d_k^T g_k}}{\left[\frac{g_{k+1}^T y_k}{d_k^T g_k} + \frac{\|g_{k+1}\|^2}{(\delta_{\alpha k} g_k^T d_k / \alpha_k - 3/2 d_k g_k^T)} \right]}$$

(contradiction) Due to the presence of $\|g_{k+1}\|^2$ square swelling , by simplifying we will obtain a (contradiction)

3. The Descending Characterized

Assume that the function fulfills the hypotheses, H and when α_k it satisfies the strong wolf line, then B_k^H it satisfies the formula, then the following is holding.

$$g_{k+1}^T d_{k+1} < 0, \quad \forall k$$

Proof: using the principle of mathematical induction

$$\begin{aligned} d_{k+1}^T g_{k+1} &= -g_{k+1}^T g_{k+1} + (1 - \theta_k) \frac{g_{k+1}^T y_k}{-d_k^T g_k} d_k^T g_{k+1} \\ &\quad + \theta_k \frac{\|g_k + 1\|^2}{(\delta_{\alpha k} g_k^T d_{k/\alpha k - 3/2}) d_k^T g_k} d_k^T g_{k+1} \\ y_k &= g_{k+1} - g_k \\ \|g_{k+1}\|^2 &= g_{k+1}^T g_{k+1} \quad \because \\ &= \|g_k + 1\|^2 - \frac{g_{k+1}^T (g_{k+1} - g_k)}{d_k^T g_k} d_k^T g_{k+1} + \theta_k \frac{g_{k+1}^T (g_{k+1} - g_k)}{d_k^T g_k} d_k^T g_{k+1} + \theta_k \frac{\|g_{k+1}\|^2}{(\delta_{\alpha k} - 3/2) g_k^T d_k} d_k^T g_{k+1} \\ \because 0 &\leq \theta_k \leq 1 \\ &= \|g_k + 1\|^2 - \frac{(g_{k+1}^T g_{k+1}) - (g_{k+1}^T g_k)}{d_k^T g_k} d_k^T g_{k+1} + \theta_k \frac{(g_{k+1}^T g_{k+1}) - (g_{k+1}^T g_k)}{d_k^T g_k} d_k^T g_{k+1} \\ &\quad + \theta_k \frac{\|g_{k+1}\|^2}{(\delta - 3/2) g_k^T d_k} d_k^T g_{k+1} \\ &= \|g_k + 1\|^2 - \frac{\|g_k + 1\|^2 - \psi \|g_k + 1\|^2}{d_k^T g_k} - \sigma d_k^T g_k + \theta_k \frac{\|g_k + 1\|^2 - \psi \|g_k + 1\|^2}{d_k^T g_k} - \sigma d_k^T g_k + \theta_k \frac{\|g_k + 1\|^2}{(\delta - 3/2) g_k^T d_k} \\ &\quad - \sigma d_k^T g_k \end{aligned}$$

Use the (SWC) search $\sigma d_k^T g_k \leq d_k^T g_{k+1} \leq -\sigma d_k^T g_k$

$$g_{k+1}^T g_k \leq -\psi \|g_{k+1}\|^2 \quad (\text{AL-Bayat i\& Jameel-2014})$$

$$\begin{aligned} &= \|g_k + 1\|^2 - \|g_k + 1\|^2 - \psi \|g_k + 1\|^2 - \sigma + \theta_k \|g_k + 1\|^2 - \psi \|g_k + 1\|^2 - \sigma + \theta_k \frac{\|g_k + 1\|^2}{(\delta - 3/2)} \\ &\quad - \sigma \end{aligned}$$

$$d_{k+1} g_{k+1} \leq -[1 - 1 - \psi - \sigma \theta_k - \sigma + \frac{\theta_k}{(\delta - 3/2)} - \sigma] \|g_k + 1\|^2$$

$$\because c_1 = -\left[1 - 1 - \psi - \sigma \theta_k - \sigma + \frac{\theta_k}{(\delta - 3/2)} - \sigma\right] \quad 0 < c_1 < 1$$

$$d_{k+1} g_{k+1} \leq -c_1 g_{k+1} g_{k+1}$$

4. Global Convergence

f A uniformly convex function

$$\lim_{k \rightarrow \infty} \inf \|g_k\| = 0$$

$$0 \leq \theta \leq 1 \therefore$$

it is obtained from the strong wolff line $\|\delta_k\|$ approaching zero, as there is an on-negative number $x_k > 0$ so that

$$\|g_k\|^2 \geq n_1 \|\delta_k\|^2$$

$$\|g_{k+1}\|^2 \geq n_1 \|\delta_k\|^2$$

Since d_k the convergence vector and obtain $\alpha k > 0$ is the step length, we through the strong wolff line if

$$\sum_{k \geq 1} \frac{1}{\|d_{k+1}\|^2} < \infty$$

$$\therefore \lim_{k \rightarrow \infty} \inf \|g_k\| = 0$$

Proof:

$$B_k^{MR} = (1 - \theta_k) B_k^{LS} + \theta_k B_k^{Ha}$$

$$B_k^{MR} = (1 - \theta_k) \frac{g_{k+1}^T y_k}{-d_k^T g_k} d_k + \theta_k \frac{\|g_{k+1}\|^2}{(f_{k+1} - f_k/\alpha k - 3/2) d_k^T g_k} d_k$$

$$B_k^{MR} = \frac{g_{k+1}^T y_k}{-d_k^T g_k} d_k + \theta_k \frac{\|g_{k+1}\|^2}{(f_{k+1} - f_k/\alpha k - 3/2) d_k^T g_k} d_k$$

$$B_k^{MR} = \frac{\|y_k\|^2}{-d_k^T g_k} + \frac{\|g_{k+1}\|^2}{\delta_{\alpha k} d_k^T g_k}$$

$$\therefore \|y_k\| = \|g_{k+1} - g_k\| \leq L \|S_k\|$$

$$g_k^T d_k \leq -c \|g_k\|^2$$

$$B_k^{MR} \leq \frac{L^2 \|S_k\|^2}{c \|g_k\|^2} + \frac{\|g_{k+1}\|^2}{\delta_{\alpha k} d_k^T g_k}$$

$$B_k^{MR} \leq \frac{L^2 \|S_k\|^2}{c \|g_k\|^2} + \frac{\|g_{k+1}\|^2}{\delta_{\alpha k} c \|g_k\|^2}$$

$$B_k^{MR} \leq \frac{L^2 \|S_k\|^2}{c n_1 \|S_k\|^2} + \frac{n_1 \|S_k\|}{n_2 \|S_k\|^2}$$

$$B_k^{MR} \leq \frac{L^2}{c n_1} + \frac{n_1}{n_2 \|S_k\|}$$

$$d_{k+1} = -g_{k+1} - B_k^{MR} d_k$$

$$\|d_{k+1}\| = \|-g_{k+1} + B_k^{MR} d_k\| \leq \|g_{k+1}\| + |B_k^{MR}| \cdot \|d_k\|$$

$$\begin{aligned} \|d_{k+1}\|^2 &= \|g_{k+1}\|^2 + 2B_k^{MR} \|g_{k+1}\| \|d_k\| + (B_k^{MR})^2 \cdot \|d_k\|^2 \\ &\leq n_2 \|S_k\| + 2 \left[\frac{L^2 \|S_k\|}{cn_1 \|S_k\|} + \frac{n_1}{n_2 \|S_k\|} \right] n_2^{y_2} \|S_k\|^{y_2} \frac{\|S_k\|}{|\delta_{\alpha k}|} + \left[\frac{L^2 \|S_k\|}{cn_1 \|S_k\|} + \frac{n_1}{n_2 \|S_k\|} \right]^2 \frac{\|S_k\|^2}{|\delta_{\alpha k}|} \end{aligned}$$

But

$$\|S_k\| = \|x_{k+1} - x_k\|$$

$$D = \text{Max} \{ \|x_{k+1} - x_k\|, \forall x, x_k \in S \}$$

$$\leq n_2 D + 2 \left[\frac{L^2 D}{cn_1} + \frac{n_1}{n_2} \right] n_2^{y_2} \frac{D^{y_2}}{|\delta_{\alpha k}|} + \left[\frac{L^2 D}{cn_1} + \frac{n_1}{n_2} \right]^2 \cdot \frac{1}{|\delta_{\alpha k}|^2}$$

$$\therefore \|d_{k+1}\|^2 \leq \psi$$

$$\sum_{k \geq 1} \frac{1}{\|d_{k+1}\|^2} \geq \sum_{k \geq 1} \frac{1}{\psi} = \frac{1}{\psi} \sum 1 = \infty \quad (9)$$

$$\therefore \lim_{k \rightarrow \infty} \inf \|g_k\| = 0.$$

5-Numerical Tests

The following part will analyse the results of our numerical experiments that employed the hybrid MR method. In addition, we will compare these results with the numerical outputs of two other algorithms (Hanan, LS) that utilise the Wolfe line search method. The comparison will be conducted using the metrics of iteration count (NoI) and function evaluation count (NoF). The iterations will stop when the magnitude of the gradient norm is less than or equal to 10^{-6} .

Furthermore, we utilized 30 unconstrained optimization problem functions with a variable count of either 100 or 1000. All the graphs in this work were generated using Fortran software. The discussion the results by Dolan and More miner to compare based on MATLAB program.

We conclude the practical aspect by reviewing the graphics related to the policy of comparisons by researchers Dolan and More. The first drawing showed the differences between the new algorithm and the classic algorithms regarding the number of iterations. The second drawing was for standard function calculations.

Figure 1: NoI comparsion.

We have observed that our strategy has transitioned to an ascending trajectory in contrast to the previous method.

Figure 1: NoF comparison.

6-Conclusion

In this study, a novel strategy called β_k^H was created for unconstrained optimisation. It combines the algorithms β_k^{LS} and β_k^{Hanen} to create a hybrid conjugate gradient method. The suggested method has undergone thorough theoretical and practical analysis. The algorithm's features of adequate descent and global convergence have been confirmed by applying certain hypotheses.
